

# Coccidioidomycosis in Rheumatologic Patients

Susan E. Hoover, MD

# The problem

Prevalence of rheumatoid arthritis is 1%

Population of Arizona is 6 million

At least 150,000 new cocci infections yearly

DMARDs and BRMs improve disease  
outcomes

There are no guidelines for managing cocci in  
these patients

# Studies of cocci in rheumatic disease

Bergstrom et al Arthritis & Rheumatism 2004

## 1. Chart review 1998-2003

13 cases of cocci in patients taking TNF antagonists

12 infliximab (11 with methotrexate)

1 etanercept

All had pneumonia

4 had disseminated disease

2 had a prior history of cocci and their disease was thought to represent reactivation

## 2. Retrospective cohort study 2000-2003

985 patients with RA, JRA, psoriatic arthritis, reactive arthritis

11 developed symptomatic cocci (1%)

7/247 on infliximab

4/738 on etanercept

# Studies of cocci in rheumatic disease

Mertz and Blair Ann NY Acad Sci 2007

Retrospective chart review 2000-2006

854 rheumatology patients

16 developed cocci (1.9%)

- 6 on infliximab

- 1 on etanercept

- 2 were disseminated (both articular, neither on TNF inhibitor)

- 2 were asymptomatic

- Most common rheumatic dx was RA

The seasonal pattern and increasing incidence 2000-2006 suggested that most cases were new infections

# Studies of cocci in rheumatic disease

Mueller et al American College of Rheumatology 2007

Chart review of 298 patients on BRMs

20 developed cocci (6.7%)

13 on infliximab (10.6%)

3 on etanercept (2.9%)

4 on adalimumab (3.3%)

3 were asymptomatic

4 were disseminated

“Control group” of 225 patients on methotrexate

4 developed cocci (1.3%)

Limitations: capturing the denominator?

# Conclusions and questions

There is a significant (1% or higher) incidence of cocci in patients on TNF inhibitors and other drugs for rheumatic diseases

Disseminated disease appears more common than in the general population

How should we manage these patients during and after cocci infection?

Can we resume BRM or DMARD therapy?

# Subsequent Therapy of Patients with Biologic Response Modifiers or Disease-Modifying Antirheumatic Drugs after Coccidioidomycosis

November 8, 2011

# Methods

## Retrospective chart review

Developed cocci while on DMARDs or BRMs

Seen at least once in a University-affiliated or Veterans Administration outpatient rheumatology clinic in Tucson, Arizona between 2007-2009

Charts were reviewed up to June 1, 2011

Mode of diagnosis, clinical manifestations, antifungal therapy and duration, and management of BRM/DMARDs

# Results

485 charts reviewed (344 University, 144 VA)

**44** patients developed cocci during treatment with a BRM and/or DMARD

6 Asymptomatic

29 Pulmonary

9 Disseminated

Skin: 4

Joint: 2 (knee, ankle)

Meningitis: 1

Lymph node: 1

Larynx: 1

# Results

20 Male, 24 Female

60-79 yrs

Caucasian

Rheumatoid Arthritis

33 RA

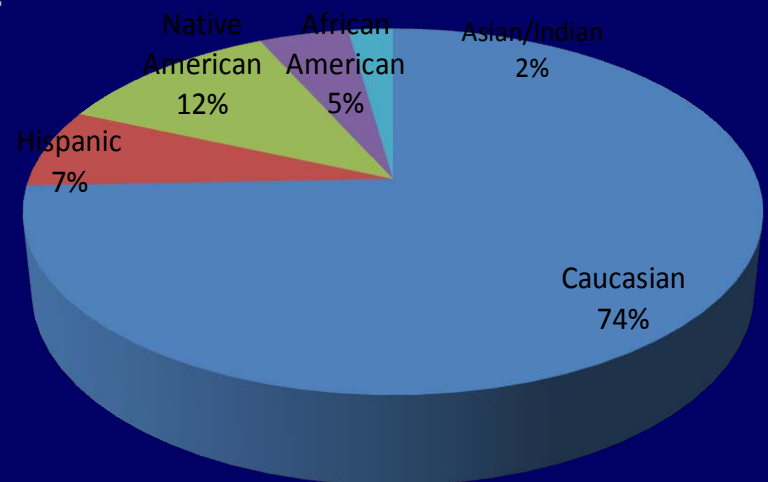

4 AS

3 PsA

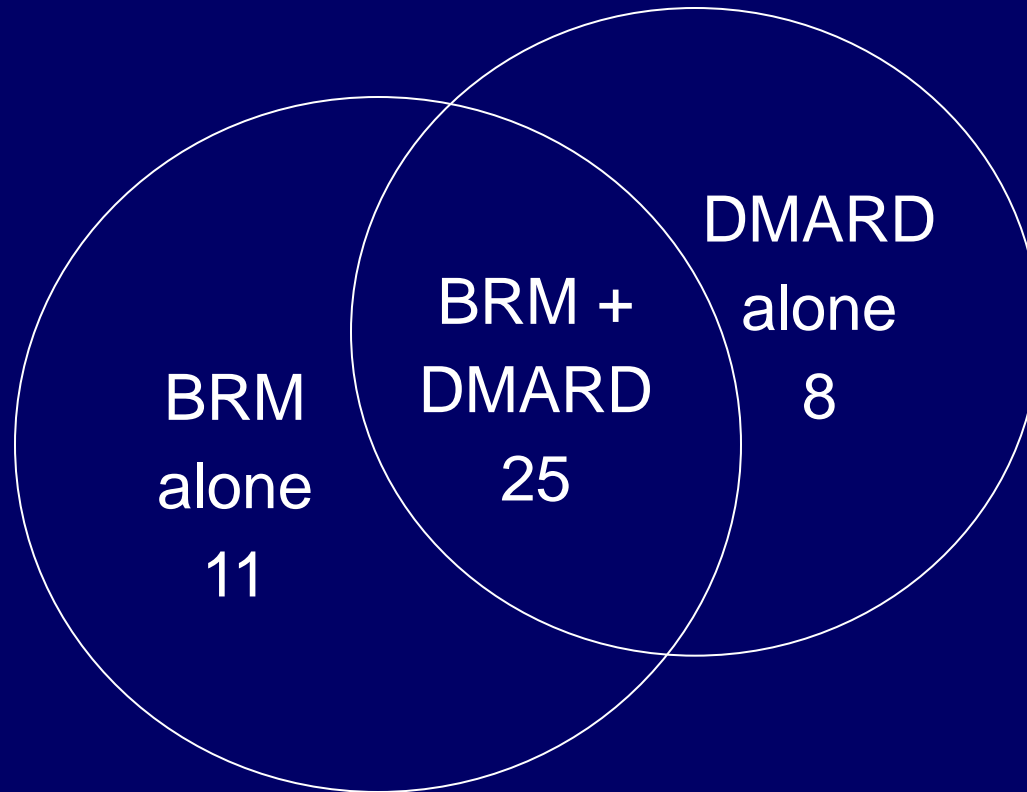

2 IBD SpA

1 SLE

1 other

# Medications at time of diagnosis

# BRMs at time of diagnosis

Most common: Infliximab

Biologic Response Modifier (total)	BRM alone	BRM in combination with DMARD
Infliximab (21)	10	11
Etanercept (6)	1	5
Adalimumab (8)	0	8
Abatacept (1)	0	1

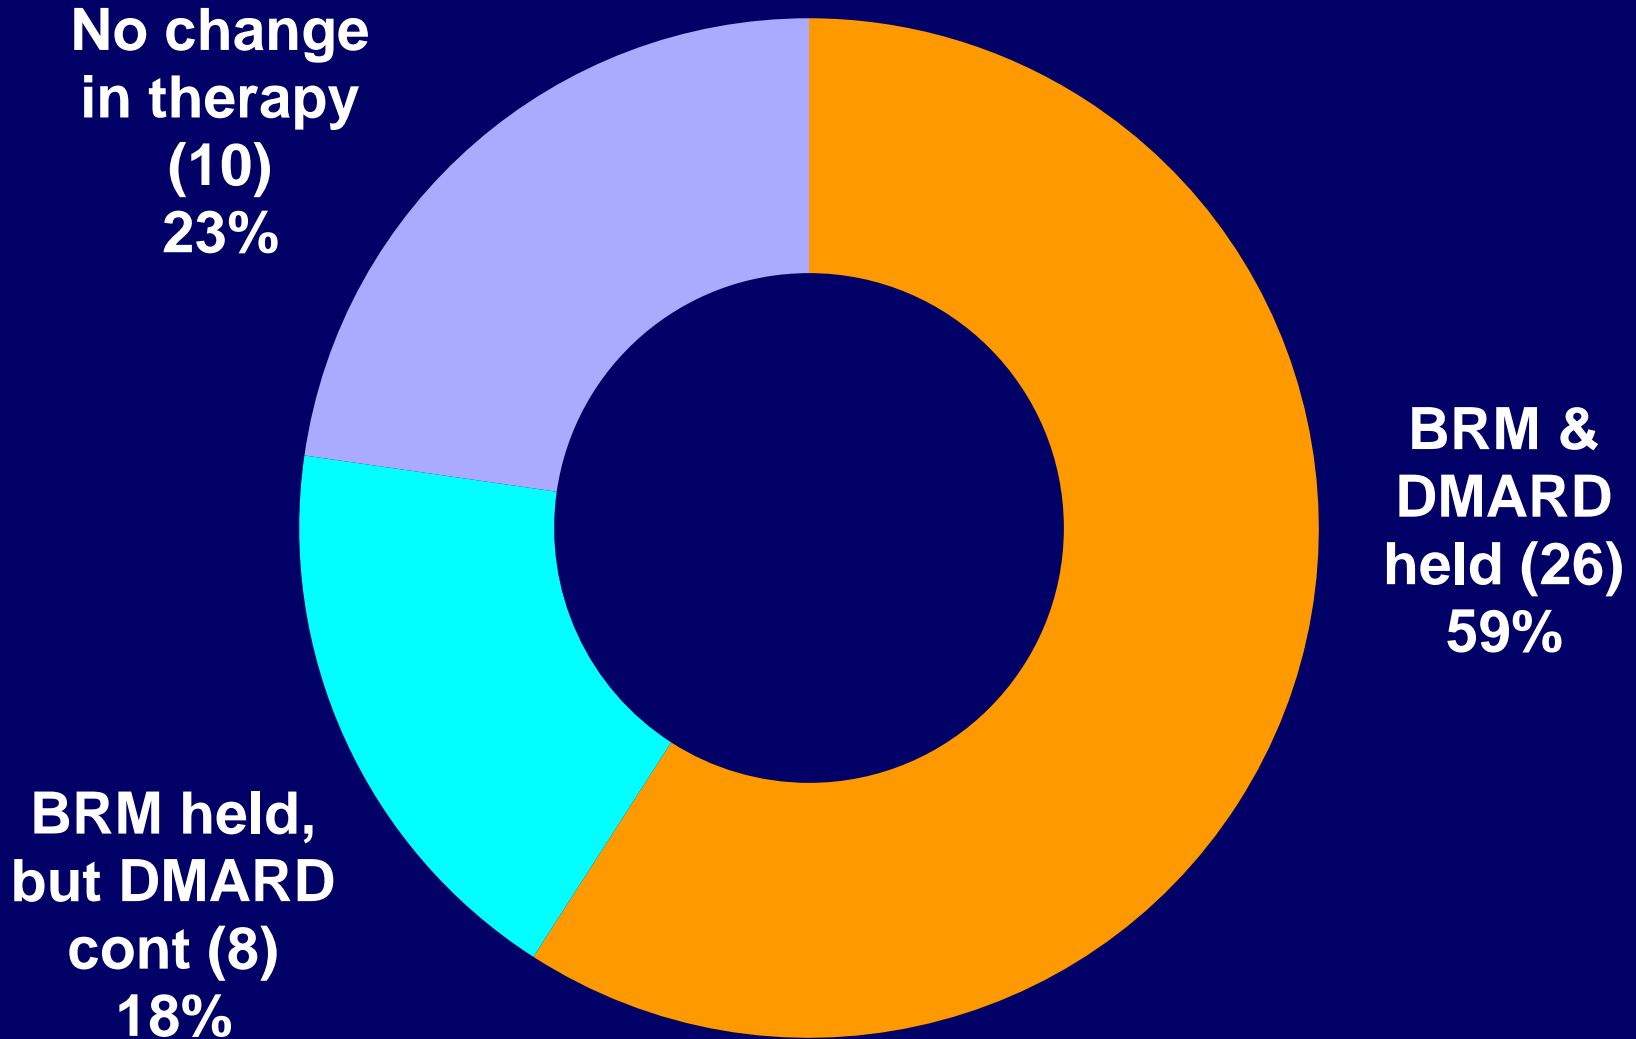

**No particular agent seemed to be associated with dissemination**

# DMARDs at time of diagnosis

Most common: Methotrexate (MTX) alone or in combination

DMARD (total)	DMARD alone	In combination with BRM
Methotrexate (26)	5	21
Azathioprine (5)	3	2
Leflunomide (2)	0	2

# Initial BRM/DMARD Management

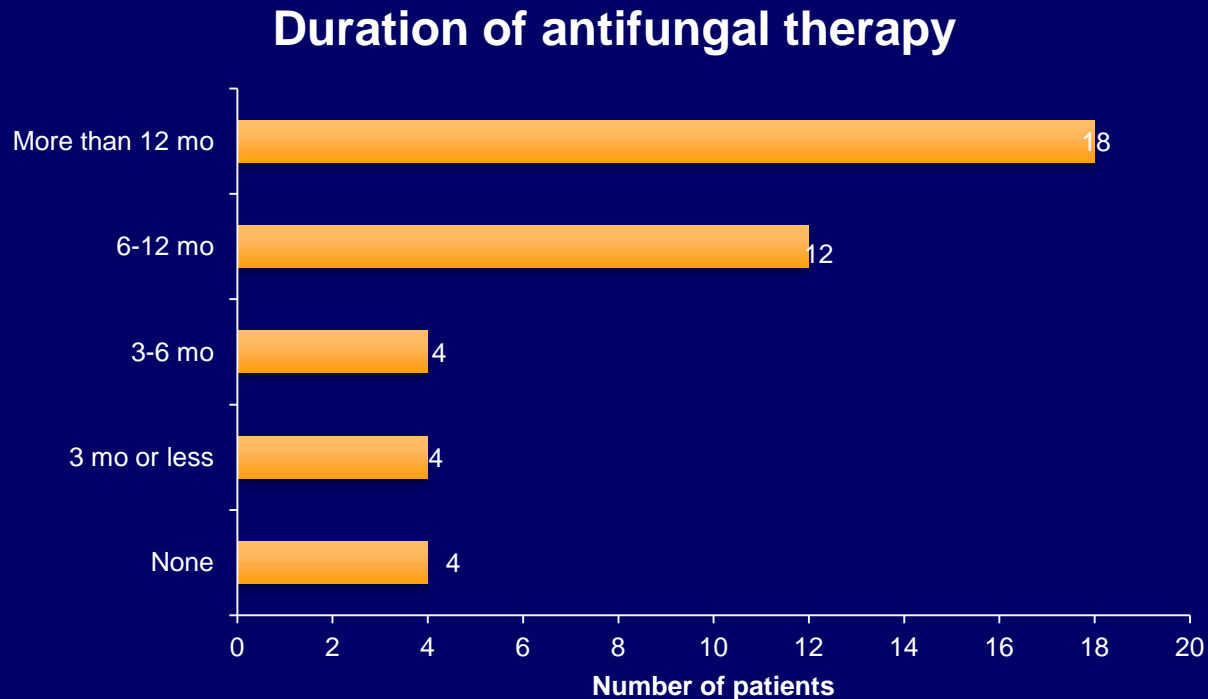

# Initial Antifungal Therapy

All but 3 patients had antifungal therapy initiated for 3 months or longer (fluconazole 400 mg/day)

Median duration was 12 months

Range 0 – 96 months

# Subsequent BRM/DMARD Management

Follow-up data were available for 38/44 patients  
33/38 patients had resumed or continued BRM  
and/or DMARD

23 restarted BRM +/- DMARD; 10 DMARD alone

Disseminated disease:

4 BRM + DMARD

4 DMARD alone

5 patients did not restart BRM/DMARD: remission of  
rheumatic disease (4), dissemination (1)

**No complications from cocci to date** (median f/u 30 mo)

# BRM/DMARD Rationale

BRM/DMARD continued at time of initial infection

Cocci asymptomatic

Active rheumatic disease

BRM/DMARD later restarted

Active rheumatic disease

# Time to Restart DMARD/BRM

## DMARD

Range: 0-48 months

Median: 1 month

## BRM

Range: 0-72 months

Median: 10 months

# Antifungal Therapy

16/33 received BRM/DMARD WITH  
antifungal therapy

5 DMARD alone

11 BRM +/- DMARD

17/33 received BRM/DMARD WITHOUT  
antifungal therapy

5 DMARD alone

12 BRM +/- DMARD

# Antifungal Therapy Rationale

Continuing antifungal while on BRM/DMARD:

- Persistent positive serologies

- Dissemination

Stopping antifungal while on BRM/DMARD:

- Negative serology

- Adverse reaction

# A Proposed Algorithm

Cocci can be serious infection in patients on  
BRM/DMARDs

How do I manage the initial infection?

Can I resume BRM/DMARD therapy?

# Initial Cocci Infection

## Asymptomatic

- Consider continue BRM/DMARD if rheumatic disease active
- Antifungal therapy 6-12 months
- Closely monitor

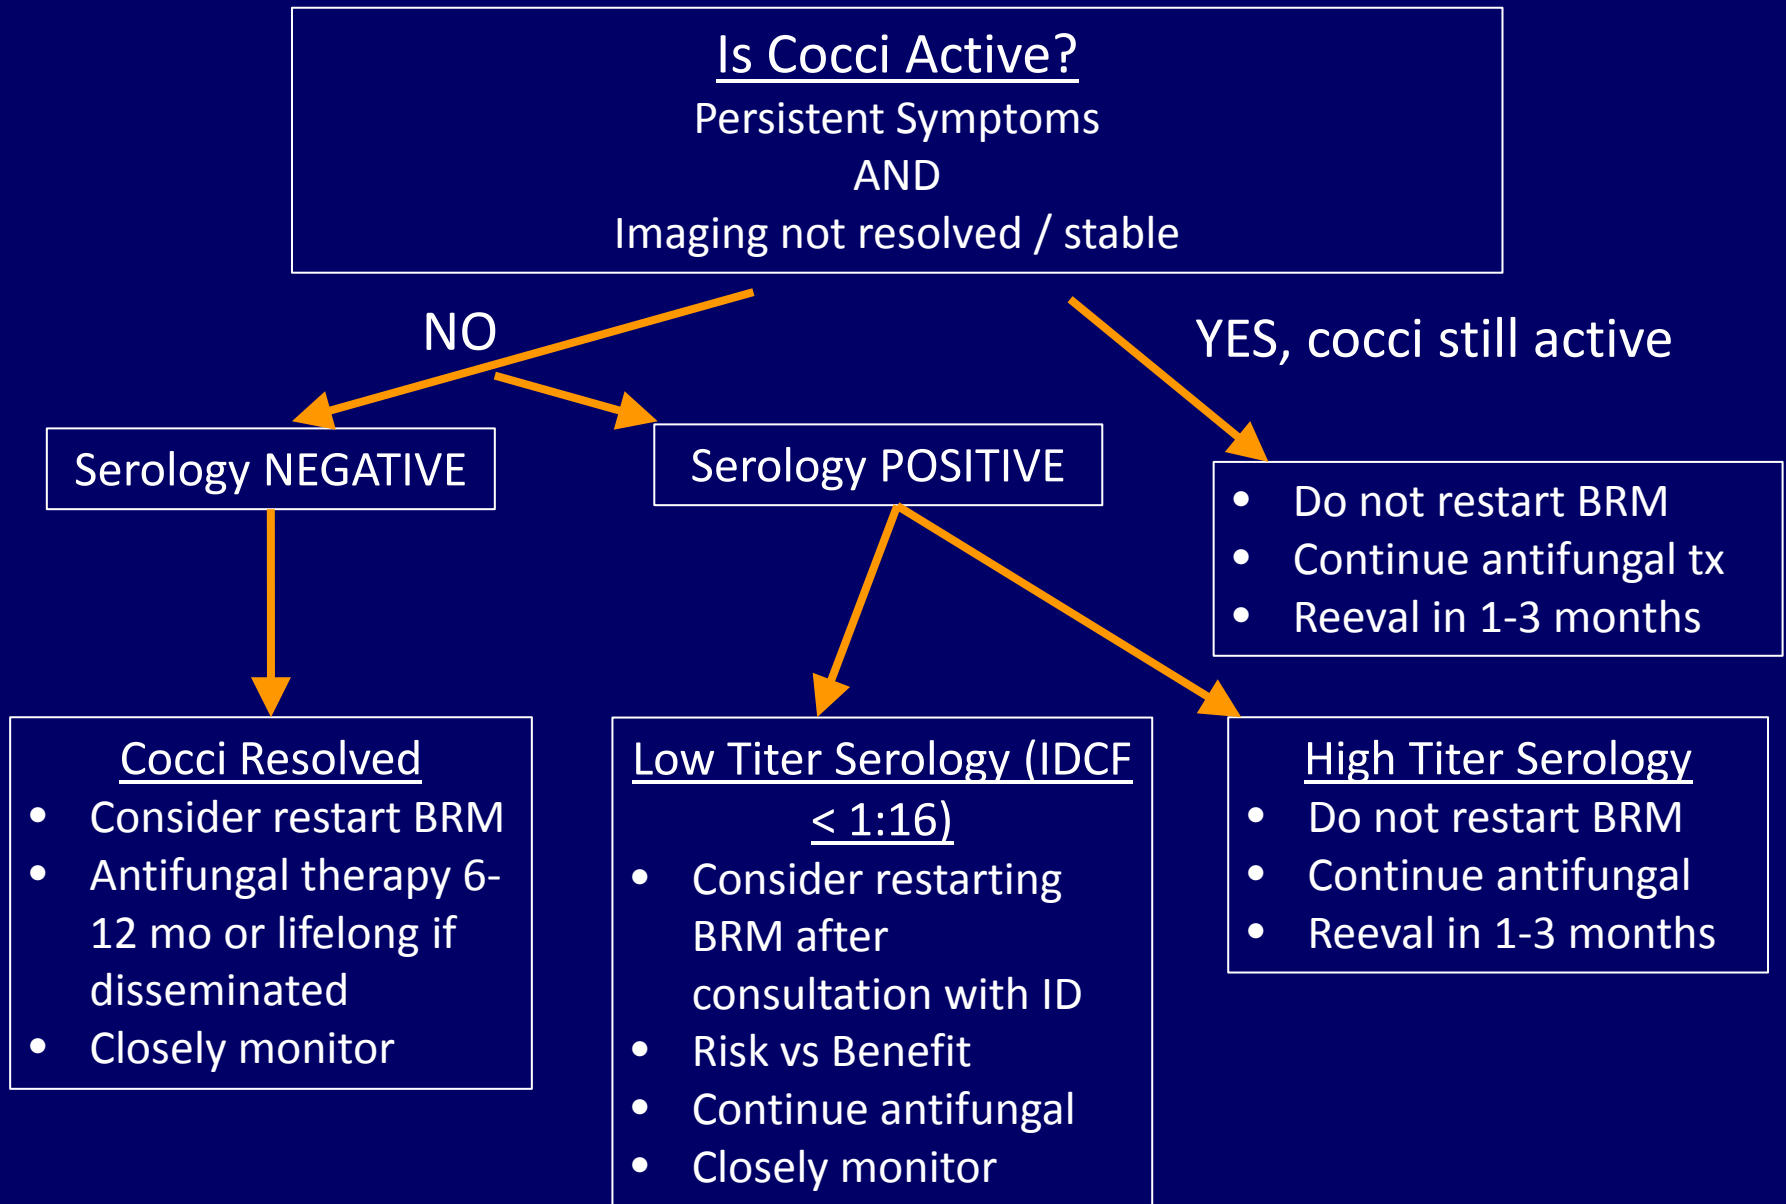

## Pulmonary

- Hold BRM
- Consider continue DMARD if mild infection and rheumatic disease active
- Antifungal therapy at least 6-12 months or until resolved
- Closely monitor

## Disseminated

- Hold DMARD & BRM
- Antifungal therapy indefinitely
- Closely monitor

# Subsequent BRM Therapy

# Conclusions

Treating with a BRM and/or DMARD after cocci infection appears to be safe in some patients

All patients should receive initial antifungal therapy; however concomitant antifungal when resuming BRM/DMARD must be an individualized decision

Larger studies with longer follow up are indicated to further characterize the relationship between BRM/DMARD therapy and this endemic fungal infection
